Central Processing Unit (CPU)

The architecture of a generic microcontroller is shown in Figure 1. Program Memory is required to retain code/programs, and Data Memory is needed to store inputs and process program code instructions. Digital input/output devices may be connected as well as analogue variants of these. Counters, timers and data/address buses interact with all of these components, in addition to the core CPU elements. A precise clock circuit provides timing/synchronisation pulses to the device.

The chip pinout for a PIC16F690 microcontroller is shown in Figure 2, and a full block diagram of the architecture is given in Figure 3.

- Note** 1: When an I/O register is modified as a function of itself (e.g., `MOVf PORTA, 1`), the value used will be that value present on the pins themselves. For example, if the data latch is '1' for a pin configured as input and is driven low by an external device, the data will be written back with a '0'.
- 2: If this instruction is executed on the TMR0 register (and where applicable, $d = 1$), the prescaler will be cleared if assigned to the Timer0 module.
- 3: If the Program Counter (PC) is modified, or a conditional test is true, the instruction requires two cycles. The second cycle is executed as a `NOP`.
